## INTRODUCTION

Phillips Alaska desires to continue gathering pre-development data on fish inhabiting lakes and streams in and around the eastern NPR-A region and the Colville River delta (Figure 1). The information gathered during the 2000 Fish Survey will be used to support requests for permits and assist with designing, siting and scheduling of facilities and activities.

Previous surveys in the region have shown that many lakes across the region contain an abundance and diversity of fish species (McElderry and Craig 1980, Bendock and Burr 1986, Moulton 1994, 1996). Lakes deep enough to retain water through the winter usually contain fish, for example only 2 of 75 lakes sampled within the delta between 1991 and 1995 did not produce fish. The fish fauna is dominated by ciscoes and whitefish (Coregonus sp.), with least cisco, broad whitefish and humpback whitefish typically representing a majority of the catch. Other species commonly encountered include round whitefish, ninespine stickleback, burbot, Alaska blackfish, fourhorn sculpin and rainbow smelt. The dominant species, least cisco, has a variety of growth forms that are readily distinguishable (Moulton 1994, 1996) and may represent 1) adaptation to varying lake productivity or 2) different dispersal episodes.

## Study Objectives

The objectives of the survey were to:

1) conduct an inventory of fish species in the various lakes and streams within the project study areas (sampling areas identified on Figures 1 and 2),
2) obtain information on relative abundance of species in different water bodies sampled, especially from lakes that may be proposed for water withdrawal during exploration and field development,
3) obtain basic descriptive population data for the species captured,
4) obtain bathymetric (i.e. depth) data to estimate lake volumes, and
5) obtain water quality measurements to assess suitability of water for potential uses.

## Approach

## Habitats Sampled

The study was confined to lakes and streams within sampling areas identified on Figure 1. Many of the lakes in these areas have water depths in excess of 7 feet, thus may provide habitat suitable for year-round use by fish. Several streams also exist in the study areas and may provide areas for seasonal use. The study began after ice melted from the lakes in early July and continued into early

August.
Areas investigated include:

1) areas in eastern NPR-A scheduled for oil exploration in 2000/2001,
2) lakes with special study needs in the Alpine Development Area.

## Eastern NPRA Area

Fish Survey. The 2000 field effort continued sampling begun in 1999 in the NPRA Exploration Area (see figures). The NPRA area lies between the Nechelik Channel of the Colville River and the vicinity of the confluence of Fish and Judy creeks. Lakes in the area may be desirable sources of freshwater during oil exploration. Water withdrawal will need to consider potential impacts to fish that depend on an adequate water supply for surviving winter. Streams in the area may be crossed by ice roads during winter. An understanding of winter dynamics in these streams will be needed to minimize effects to fish. The inventory of fish and fish habitat will provide information for assisting permitting decisions regarding water use and ice road routing. In addition, streams in the area will likely be crossed by ice roads, so an understanding of potential overwintering areas is also desirable.

The surveys in lakes consisted of short-duration gill net sampling in July and August.
Bathymetic and Water Quality Data. Bathymetric and water quality data were collected in conjunction with fish sampling. The bathymetric information allows estimating lake volumes. Water quality parameters measured include water temperature, specific conductance, dissolved oxygen, and pH .

## Alpine Lake Studies

Fish Populations. Lakes L9313 and L9312 were sampled during 2000. These lakes are used as camp water sources for the Alpine Development. Both lakes support populations of fish that are harvested for subsistence or form important links in regional food chains. The Alaska Department of Fish and Game (ADF\&G) permit for water withdrawal requires that the fish populations be monitored twice during the ice-free season for 3 years after project start-up to assess the viability of the populations.

In 1999, sites suitable for monitoring with fyke nets were identified and initial information on the fish populations was obtained. The sampling during 2000 provides the first information on the populations after one winter of water withdrawal

Water Quality Data. Water quality parameters measured include water temperature, specific conductance, dissolved oxygen, and pH .

## METHODS

## Gear Utilized

The sampling strategy was to use gill nets in perched lakes that were sampled for the first time and fyke nets in lakes that were subjected to long-term monitoring. Gill nets used were those used in previous surveys in the region ( 120 feet long, six panels of variable mesh, mesh size ranging from 1 to 3.5 inches stretched mesh). Data gathered in 1995-1997 indicate that fyke nets are relatively inefficient in perched lakes within the delta, particularly for sampling least cisco and broad whitefish. In order to avoid entangling waterfowl in the gill nets, the strategy was to have each gill net set limited to 4-6 hours duration and have a person tend each net to ensure waterfowl do not approach the net. The person monitored the net continuously for the duration of the set.

Fyke nets were those employed during previous Colville Delta fish studies, with a $3 x 4 \mathrm{ft}$ frame ( $3 / 8^{\prime \prime}$ mesh in body), 25 ft wings, and 50 ft lead ( $3 / 4^{\prime \prime}$ mesh in wings and lead).

## Biological and Physical Data

Data collected include catch rate and size data for each species captured in each set made. Associated data include beginning and end time of each set, type of gear utilized, water temperature, conductivity or salinity, and any relevant observations. Fish were counted by species and measured to the nearest millimeter fork length. Prior to measuring samples from fyke nets, the fish were anesthetized in MS-222, and after measuring they were allowed to recover in a holding pen prior to release.

Depth surveys were be made of the lakes and channels surveyed to assess the potential for winter survival.

## Analysis

Data analysis included a description of the catch from each sample site, with the associated population data. Fish catches were presented as catch per effort to reveal differences in relative abundance. The information was presented by sample site and by habitat type.

Historical data from previous sampling in the Colville Delta and other nearby areas, such as Dease Inlet, Teshekpuk Lake and the Prudhoe Bay region, are used for comparative assessment of the findings.

Lake volume estimates for one-time withdrawals are made by calculating the volume of a cone
using the lake area for the base and the maximum observed depth for the height. The estimated area for each lake is obtained from a GIS base map. For lakes where there is a fish concern, a correction is made to ensure that fish can survive the winter. The maximum depth is reduced by 7 feet prior to making the volume calculation to account for the expected maximum ice thickness during winter $-15 \%$ of the this revised estimate is then available for withdrawal.

## SUMMARY OF RESULTS

## NPR-A Lakes

A total of 28 lakes were sampled for the first time in NPR-A in 2000 (Table 1). Two lakes surveyed in 1999 were re-visited. Much of the sampling was upstream of the confluence of Fish Creek and Judy Creek, with much of the sampling in lakes along each of the streams. In contrast to 1999, fish densities were very low and often non-existent, despite much longer fishing times (Tables 2 and 3). It seems clear that upstream from the confluence of these creeks, fish do not make significant use of lake habitat. As observed in 1999, fish use of lakes near and downstream of the confluence is quite high for those lakes near the creeks and for those lakes connected to the creeks by streams. Water chemistry parameters measured in 2000 are provided in Table 4.

## Alpine Lakes Studies

Water use from lake L9313 during winter 1999/2000 was 5.9 million gallons, or $85 \%$ of the permitted withdrawal. In lake L9312, only 2.8 million gallons was used, or about $15 \%$ of the permitted use (Table 5).

Fyke nets were fished in lakes L9312 and L9313 from July 22 to 29, and again from August 16-22. In lake L9312, we caught 2,954 fish from 10 species, compared to 365 fish from 6 species in 1999 (Table 6). Fishing effort was twice as great in 2000, which accounts for some of the difference, but there was a dramatic increase in the number of least cisco in 2000. Humpback whitefish, Alaska blackfish and ninespine stickleback were also more numerous in 2000.

In lake L9313 we caught 1,256 fish from 6 species in 2000, compared to 1,102 from 5 species in 1999. Compared to last year, there was a noticeable lack of least cisco in L9313, and substantial increase of Alaska blackfish and ninespine stickleback (Table 6).

Length frequency data for each lake are included (Tables 7 and 8). For both L9312 and L9313, much of the increase in Alaska blackfish catch was from high catches during August, when the sun had moved below the horizon and there were periods of darkness at night. It is likely the reduced light accounted for the high Alaska blackfish catch during August.

Additional bathymetry and water chemistry data were obtained to better understand the physical and chemical dynamics of the lakes (Table 9).

*The $15 \%$ AK Volume is the volume of water that may be extracted from fish-bearing lakes. For those lakes without fish, the column "Calculated Volume" applies. ** All lakes with a " Y " in this column must be treated as fish-bearing: i.e., use the $15 \% \mathrm{AK}$ Vol column for allowable water withdrawl volumes.
While ninespine stickleback and Alaska blackfish may be present, they are not sensitive to impacts associated with lake withdrawals.
