INTRODUCTION

ARCO Alaska Inc. has increased exploration activities in the Colville Delta, Alaska and these exploration activities may lead to eventual oil field development within the delta. Delta channels and lakes may be crossed by ice roads and seismic lines during exploration projects. Permanent access to the delta, which may be required for potential field development, will necessarily cross many channels. Water may be withdrawn from lakes to support both industrial and domestic needs.

During review of both exploration and development permits, information will be required on the biological sensitivity of delta channel and lakes. Lakes of interest include both isolated lakes and those connected to river channels during the open water period, often called tapped lakes. Deep isolated lakes are likely capable of supporting fish populations while the most critical use of tapped lakes is by anadromous fish that move into these lakes in the fall and remain through the winter.

The most critical use of delta channels is by anadromous fish that move into these channels and lakes connected to the channels in the fall and remain through the winter. A substantial body of information exists for the major channels of the Colville Delta (Kogl and Schell 1974, George and Kovalsky 1986, Fawcett et al. 1986, Moulton et al. 1992). These areas support substantial fisheries in the fall and fish use of these channels is well documented. Less information is available for the minor channels that lie between the Main (Kupigruak) Channel on the east and the Nechelik (Nigliq) Channel on the west.

The study will provide physical and biological information on these habitat types to understand their use as winter habitat by various fish species. In addition, the results of the survey will be used, in concert with previous surveys within the area, to direct any future investigations that may be needed.

The objectives of the study are to document fish presence and winter habitat use in both lakes and minor delta channels. Lakes include both isolated and tapped lakes that have not been previously surveyed or had been surveyed during summer in the early to mid-1980's. Selected lakes are those that may be included in an eventual field development.

METHODS

The study consisted of 20 days of gill net sampling in lakes across the outer portion of the Colville Delta in late October to early November in 1991 and 1992 (Figure 1). The initial candidate sampling locations in lakes and delta channels were identified through inspection of maps of proposed pad locations, access roads and seismic plans prior to final design of the sampling program. Once identified, available information on lake depths was reviewed and lakes deeper than 2 m (6.5 ft) deep (i.e. likely to retain water through the winter) were selected for sampling with variable mesh gill nets set under the ice. In 1992, the thickness

of the ice by October 28 restricted sampling to lakes 2.5 m deep (8 ft) or greater. Channel profiles were measured in the field and channels greater than 2 m (6.5 ft) deep were sampled.

The variable mesh gill nets used in the sampling program consisted of a set of two nets, each with three 1.8 m (6 ft) x 6.1 m (20 ft) panels. One net contained small meshes: 25 mm (1.00"), 32 mm (1.25"), and 41 mm (1.63"), the other net contained large meshes: 52 mm (2.06"), 70 mm (2.75") and 89 mm (3.50"). Nets were checked on a daily basis unless weather prevented travel. Both nets were fished for at least one day at a location. At some locations, the nets were fished for an additional day to verify initial findings. The primary objective was to document presence or absence, thus large sample sizes were neither needed nor desired.

Since salinity affects the suitability of the over-wintering habitat, salinity was measured at each of the sampling locations. A salinity profile in 0.5 m increments was measured at the beginning or end of each set using a YSI Model 33 salinometer.

Catches were separated by mesh size and enumerated by species; fork lengths were taken for all specimens. Duration of each set was recorded to allow calculation of catch rates. Otoliths were removed from all coregonines to determine age-length relationships. Otoliths were read using the break-and-burn technique.

RESULTS AND DISCUSSION

HABITATS SAMPLED

Sampling was conducted during the periods November 1-10, 1991 and October 28-November 6, 1992. Twenty-four stations were identified for sampling (Table 1, Figure 2). Sampling stations were located with a GPS positioning system.

The sampling stations were classified as river channel (RC), tapped lake (TL), or isolated lake (IL). Aerial photography of the delta region (taken July 23, 1983) was examined to verify that the sampled lakes were or were not connected to the river during summer. The presence of turbid water in the lake was used to indicate an active connection. Five of the lakes showed obvious influence by river flow with the remaining 13 lakes all isolated from direct river influence. The remaining six stations were in river channels (Table 1).

Four of the lakes had been previously sampled by Bendock and Burr (1986) during their 1985 survey of the delta region. An additional two lakes were sampled by McElderry and Craig (1981) during the search for Arctic cisco spawning areas in 1979 and referenced by Bendock and Burr (1986). The comparable sample numbers are:

<u>1991 Station No.</u>	<u>Bendock & Burr Lake No.</u>	<u>McElderry & Craig Lake No.</u>
9102	43	
9106	39	
9107	20	20
9111	14	13
9201	41	
9205	42	

PHYSICAL CHARACTERISTICS

Elevated salinities (maximum salinities greater than 5 ppt) were measured in three of the five tapped lakes and one isolated lake:

		<u>Mean Salinity (ppt)</u>	<u>Bottom Salinity (ppt)</u>
Tapped Lakes			
Station 9102 (B&B Lake 43)			
Nov 2, 1991	12.6	17.7	
Nov 5, 1991	15.1	19.8	
Station 9105	Nov 3, 1991	7.5	10.3
	Nov 6, 1991	9.5	13.2
Station 9107 (B&B Lake 20)			
Nov 6, 1991	4.0	7.9	
Isolated Lake			
Station 9210			
Nov 3, 1992	4.2	5.5	

Bendock and Burr (1986) report a salinity of 5 ppt in Stations 9106 (Lake 39) and 9201 (Lake 41) during the summer, we measured maximums of 0 and 3.6 ppt, respectively, at the same lakes under the ice during the 1991-1992 surveys. At Station 9102 (Lake 43), Bendock and Burr (1986) reported a maximum depth of 1.8 m (6 ft), while we observed a depth of 3.7 m (12 ft) at the 1991 sample site in the same lake.

Salinities were highest in river channels with the lowest salinities being recorded in isolated lakes:

<u>Habitat Classification</u>	<u>Mean Salinity</u>	<u>Standard Deviation</u>	<u>Number of Observations</u>
River Channel	12.5	7.1	141
Tapped Lake	7.2	6.0	50
Isolated Lake	1.0	1.1	112

BIOLOGICAL FINDINGS

Biological and Habitat Patterns

Species captured were, in order of abundance, least cisco, Arctic cisco, rainbow smelt, broad whitefish, fourhorn sculpin and humpback whitefish (Table 2). Fish were captured at 21 of the 24 sites sampled. Least cisco were caught at 17 of the 24 stations, with Arctic cisco present at 15 stations. The two species together contributed 540 of the 610 fish caught (88.5 percent). Fourhorn sculpin and rainbow smelt were the third and fourth most abundant species in 1991, but were not caught in 1992. The 1991 survey focused on river channels and tapped lakes, which are habitats to which these marine-associated species would have greater access during the fall.

Catch rates varied by habitat for each captured species (Figure 3). Arctic cisco were most abundant in river channels, with decreasing abundance in tapped lakes and isolated lakes. Conversely, least cisco increased in abundance from river channel to isolated lake habitats. Broad whitefish and humpback whitefish were only found in lakes (both tapped and isolated), while rainbow smelt and fourhorn sculpin were only found in river channels and tapped lakes.

The size of Arctic cisco increased from river channel to tapped lake to isolated lake habitat (Figure 4). Arctic cisco from river channels appeared to encompass all age groups expected to be in the region, based on size composition observed in summer fyke net sampling along the Beaufort Sea coast (LGL Alaska 1992). Age data indicated that age-1 fish (1990 year class) dominated the samples (Table 3). Arctic cisco from isolated lakes were primarily large fish at 340 mm or greater, some of which had reached maturity.

The size range of least cisco indicated a broad range of sizes in all habitats (Figure 5). Age data for least cisco indicated that more than one population was being sampled. The fish from river channels and tapped lakes had similar growth rates. Least cisco captured from isolated lakes were noticeably smaller for a given age than least cisco captured from other areas, indicating reduced growth for isolated populations as compared to the anadromous form captured in river channels and tapped lakes (Figure 6). Catch rates from isolated lakes were often high, indicating populations at high density (Appendix Table 2).

Comparison with Historical Information

Bendock and Burr (1986) reported data in a summarized form, thus it is not possible to compare size and abundance data by species on specific lakes. A comparison was possible for species presence and total CPUE (Tables 4 and 5). The results are reasonably consistent across years given the limited sampling conducted in each survey, although the number of species present appeared to be less during the 1991-1992 sampling. This reduction could be a result of the late fall sampling period because fish become less active as water temperature reduces and are not as susceptible to gill nets.

McElderry and Craig (1981) provided more detail on individual lakes. They report size ranges and mean length of fish in each lake. A comparison of mean lengths and ranges for least cisco indicates remarkably little difference between the two sampling periods, i.e. 1979 and 1991-1992 (Table 6). The minor differences may be caused by differences in mesh sizes. The other species show considerable shifts in the size structure of fish sampled, which should be expected given the small sample sizes involved.

One possible change between sampling periods is a reduction in the broad whitefish at Station 9107 (Lake 20). During summer sampling in 1979, there were multiple sizes present, while in the under-ice sampling in 1991, only larger fish were present. This difference could reflect either seasonal use patterns or long-term changes in utilization of the lake.

CONCLUSIONS

The survey indicated that over-wintering areas within the minor delta channels were limited in number and likely represented a small proportion of the surface area covered by the surveyed channels. In contrast, the lakes within the delta appeared to offer substantial opportunities for over-wintering. Many of the surveyed lakes contained water in excess of 2 m, with depths to 9 m recorded.

Three of the tapped lakes and one isolated lake near the coast showed elevated salinities during November. The lakes with elevated salinities may provide marginal habitat for freshwater species, but would be suitable for anadromous species, such as Arctic cisco, least cisco and rainbow smelt, if hypersaline conditions do not develop prior to break-up.

Species composition, relative abundance and size of fish in the survey area was similar to that previously reported during summer surveys. There were no noticeable changes that would indicate fish vacate the minor delta channels and tapped lakes prior to freeze-up. The observations are consistent with the hypothesis that fish move from the delta channels into the tapped lakes to take advantage of the greater volume of water represented by the latter habitat type.

Differential use of delta habitats by the various species was indicated by the catch patterns. Arctic cisco were primarily found in river channel habitat with low catch rates of this species

in both tapped and isolated lakes. Catch rates decreased as the mean salinity of the habitat decreased. In contrast, least cisco increased with decreasing salinity, with catches lowest in river channels and highest in isolated lakes.

The survey indicated that least cisco commonly inhabit isolated lakes within the Colville Delta and are abundant in some lakes. It is likely that least cisco develop reproducing populations in lakes deep enough to maintain wintering habitat through severe winters. Broad and humpback whitefish may also be able to develop lake-resident populations, but the sample sizes were insufficient to address this point. Arctic cisco are not known to reproduce successfully in the Colville Delta, thus it is likely that most of these fish immigrate into the isolated lakes during high water and become stranded.

Species:
 ARCS = Arctic cisco
 LSCS = least cisco
 BDWF = broad whitefish
 HBWF = humpback whitefish
 RBSM = rainbow smelt
 FHSC = fourhorn sculpin

Habitat:
 RC = river channel
 TL = lake connected to a river channel
 IL = lake not connected to a river channel

Appendix Table 4. Biological data obtained from fish collected during 1991-1992 gillnet sampling in the Colville River delta.

9213	Gillnet	9201	TL	11/7/92	1130	6	2	ARCS	343	M	2	7		

Species:

ARCS = Arctic cisco

Panel 1 = 1.00 in (25 mm) mesh

LSCS = least cisco

Panel 2 = 1.25 in (32 mm)

BDWF = broad whitefish

Panel 3 = 1.63 in (41 mm)

HBWF = humpback whitefish

Panel 4 = 2.06 in (52 mm)

RBSM = rainbow smelt

Panel 5 = 2.75 in (70 mm)

FHSC = fourhorn sculpin

Panel 6 = 3.50 in (89 mm)

Habitat:

RC = river channel

TL = lake connected to a river channel

IL = lake not connected to a river channel
